

Design a spreadsheet backend which can support two operations:
You can write the code in any language and provide a main method / tests to validate the code.

```
void setCellValue(String cellId, Object value)
int getCellValue(String cellId)
```

Example:

```
setCellValue("A1", 13)
setCellValue("A2", 14)
```

```
getCellValue("A1") -> 13
setCellValue("A3", "=A1+A2")
getCellValue("A3") -> 27
```

```
setCellValue("A4", "=A1+A2+A3")
getCellValue("A3") -> 54
```

- Write this in a language of your choice
- Mention edge cases and other situations you need to handle
- Attach the response via email / GitHub repo link
